

1. Why we use IActionResult not ActionResult?
Cause it's better to implement against interface not base class and if we want to use custom class that implement IActionResult but doesn't inherit from ActionResult.
2. What is httpcontext request and response message?
Request: what the user sends to the server.
Response: what the server replies to the user.
3. What is the difference between HTTPS, HTTP?
HTTP: hyper text transfer protocol, not secured, data transferred in plain text, default port is 80.
HTTPS: hyper text transfer protocol secured, secured, data transferred encrypted, default port is 443.
4. What is the segments and fragments in URL?
 - Segments: are the parts of url separated by /, tell the server which resource is being requested -> products/electronics/laptops?id=10
 - Fragments: used to point to section inside the page, handled by the browser not the server, come after # in URL -> products/electronics/laptops?id=10#reviews
5. what's Builder and Dependency injection with a real life example clarify it?
 - Builder: a design pattern used to construct complex objects step by step, without needing to know all the details at once. → like ordering food, you order and the chef made but you don't know the details.
 - Dependency Injection: a technique to provide an object's dependencies from outside, instead of the object creating them itself. → like a car that depends on engine to work, the engine is supplied from outside, we can change it without changing anything else in the car (flexibility).
6. what's the difference btw Web Pages(Razor) and MVC and state two business cases and compare btw them
 - Web Pages (Razor): page-based model where each page is self-contained (UI + logic). → like a small shop where each worker handles everything (taking orders, cooking, serving). Simple but not scalable.
 - MVC (Model-View-Controller): architecture that separates logic, data, and UI into different layers. → like a big company where departments are specialized (sales, production, delivery). More complex but scalable and maintainable.
 - Business Case 1 (Web Pages): A bakery wants a small website (Home, Menu, Contact). Web Pages is better → fast, simple, no complex architecture.
 - Business Case 2 (MVC): An enterprise e-commerce platform (products, cart, payments, admin panel). MVC is better → scalable, team-friendly, testable.

7. what's Content type in response message and where we use it and why?

Content-Type: a header in the HTTP response that tells the client (browser/app) what type of data is being sent.

Used in server responses to specify the format of the returned data, so the client knows how to interpret the response.
